

A top-down view of a large, circular, metallic detector chamber. The interior is filled with a complex network of blue-lit structural elements and numerous bright, starburst-shaped light patterns, likely representing muon detection events. The chamber is surrounded by a concrete or metal base with various cables and components visible.

# The Physics of Muon Detection

Feel free to ask questions  
during the presentation!

# VIP project

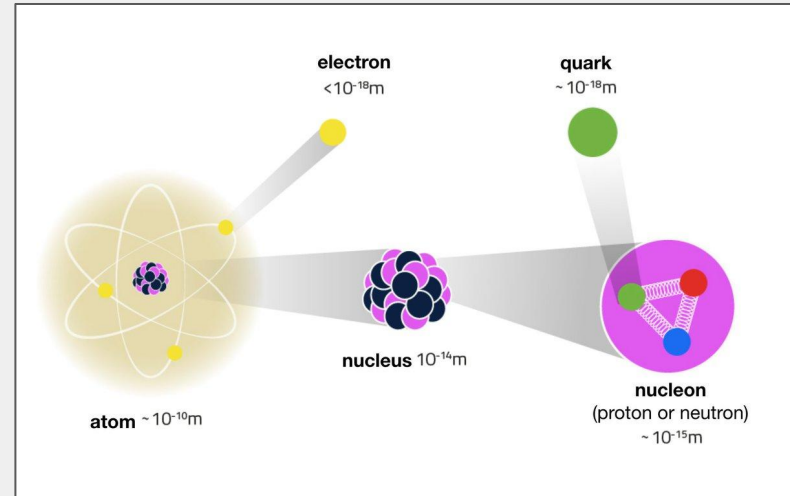

VIP (Vertically Integrated Project) is a program in the ECE Department, but this is the first time Physics is doing a VIP, with the mentorship of Dr. Frank Geurts! Our 1 semester (so far) endeavour has included learning the basics of the standard model in particle physics, the structure of particle detectors like the one at CERN, and analyzing real cosmic rays hands-on utilizing a 3 scintillator-panel muon detector!

# Standard Model

We all have a basic understanding that atoms are made of protons, neutrons, and electrons, but there is another layer to subatomic particles, and physicists use the standard model to organize them all.

mass →	$\approx 2.3 \text{ MeV}/c^2$	$\approx 1.275 \text{ GeV}/c^2$	$\approx 173.07 \text{ GeV}/c^2$	0	$\approx 126 \text{ GeV}/c^2$

# Special Relativity and Muons

Muons have a mean life expectancy of 2.2 microseconds, so if they are created in the upper troposphere and travel close to the speed of light ( $3.0 \times 10^8$  m/s), they should only be able to cover 660 meters before they decay into electrons and neutrinos. However, experimental data reveals that muons are still recorded at sea level.

This is due to the time dilation effect from the theory of Special Relativity. Because they travel at relativistic speeds, their “clocks” run slow!

# A Few Important Commands...

**H1, H2** : Help Commands, shows all the commands to set/reveal different settings.

**DS** : Display Scalars, reveals how many signals for each panel, and total valid events counted (coincidence).

**CE** : Counters Enable, starts reading data out.

**RB, RE** : Reset Board, Reset Everything

# Calibrating Voltages:

In order to make sure we are getting a significant amount of signals and reduce noise, we must calibrate high voltage values and threshold voltage values for each panel, respectively.

The way we can find the right value to set both is by plotting a graph...

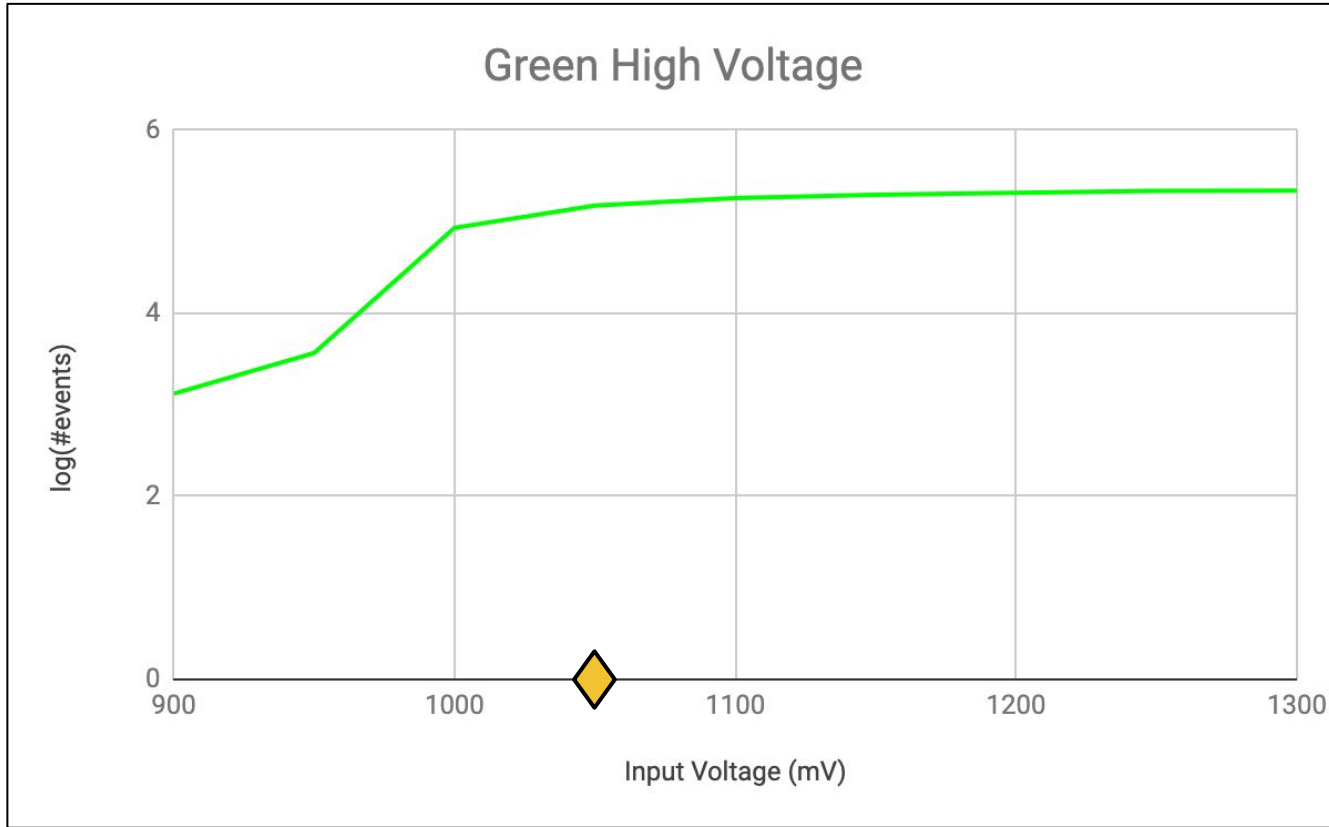

# High Voltage

This is the voltage we apply to the PMT to amplify signals so we can easily detect the slightest proton creation.

You can change the voltage by turning the square knobs and check the voltage with a digital multimeter!

# Finding the right high voltage for a panel:

# Threshold Voltage

Because we applied a high voltage, the noise signals are also amplified, so we must use a **threshold** to set a level under which we do not accept signals.

Command to change threshold:

```
TL #counter #milivolts
```

Example for setting the 1st counter to 1300 mV is:

```
TL 0 1300
```

# Finding the right threshold for a panel:

# Experiments with the Detectors: Flux

This setup can show if and how flux is affected by external factors (air pressure, temperature, et cetera).

Coincidences:  
1-fold, 2-fold, 3-fold

For example, 2-fold meaning a muon hitting at least 2 detectors within an almost simultaneous period of time.

# Commands to set coincidence levels:

WC 00 #coincidence level #which counters are enabled

For example, 2-fold coincidence with the first and third counters enabled is:

WC 00 1A

#counters enabled is in HEX, convert to Binary:

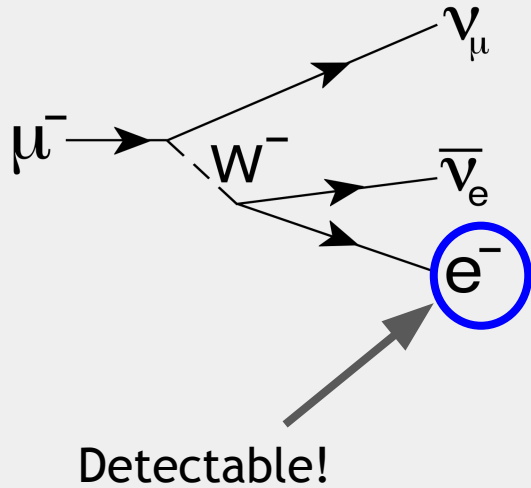

Channel:	0	1	2	3
Decimal Value:	8	4	2	1

# Experiments with the Detectors: Shower

Coincidences between counters at the same altitude, but can be counters from different schools/locations.

# Experiments with the Detectors: Lifetime

# How do we make sure it's an electron?

By manipulating the range of time in which a signal is accepted!

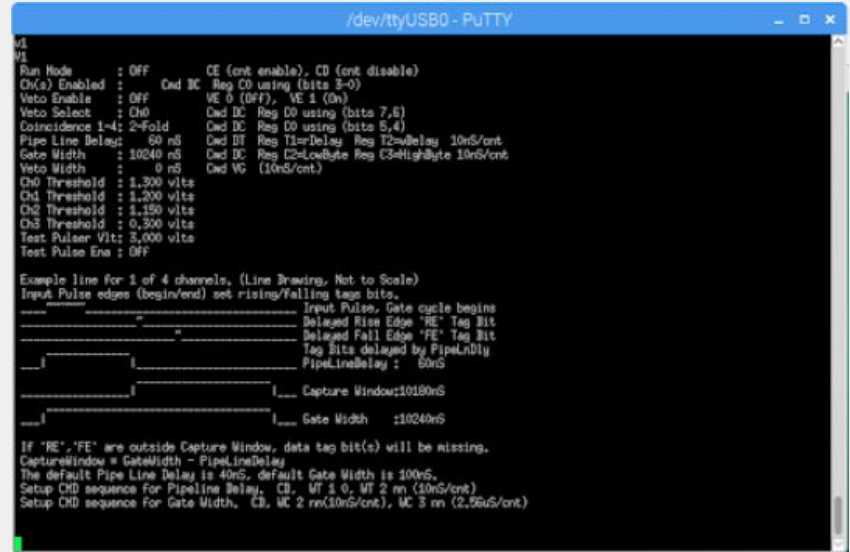

(And by choosing to cut out events that have a 3rd signal).

# Changing the “d” and “W”:

The default values for d and W are 4 (40 ns) and 10 (100 ns), respectively (10 ns bins).

For lifetime measurements, the W will be much larger at 400 HEX (10240 ns).

```

v1
Run Mode      : OFF      CE (cnt enable), CD (cnt disable)
On(a) Enabled : OFF      Cnd IC Reg CD using (bits 3-0)
Veto Enable   : OFF      VE 0 (OFF), VE 1 (On)
Veto Select   : Ch0      Cnd DC Reg D0 using (bits 7,6)
Coincidence 1-4: 2-Fold  Cnd DC Reg D0 using (bits 5,4)
Pipe Line Delay: 60 ns   Cnd DT Reg T1=Delay Reg T2=Delay 10ns/cnt
Gate Width    : 10240 ns Cnd DC Reg C2=LowByte Reg C3=HighByte 10ns/cnt
Veto Width    : 0 ns     Cnd VG (10ns/cnt)
Ch0 Threshold : 1,300 vits
Ch1 Threshold : 1,200 vits
Ch2 Threshold : 1,150 vits
Ch3 Threshold : 0,300 vits
Test Pulse Vlt: 5,000 vits
Test Pulse Ena : OFF

Example line for 1 of 4 channels. (Line Drawing, Not to Scale)
Input Pulse edges (begin/end) set rising/falling tags bits.
_____ Input Pulse, Gate cycle begins
_____ Delayed Rise Edge "RE" Tag Bit
_____ Delayed Fall Edge "FE" Tag Bit
_____ Tag Bits delayed by PipeLineDelay
_____ PipeLineDelay : 60ns
_____ Capture Window:10180ns
_____ Gate Width :10240ns

If "RE", "FE" are outside Capture Window, data tag bit(s) will be missing.
CaptureWindow = GateWidth - PipeLineDelay
The default Pipe Line Delay is 40ns, default Gate Width is 100ns.
Setup CHD sequence for Pipeline Delay, CB, MT 1 0, MT 2 nn (10ns/cnt)
Setup CHD sequence for Gate Width, CB, MC 2 nn(10ns/cnt), MC 3 nn (2,56us/cnt)
```

Commands in HEX:

**d**  
WT 02 **04**

**W**  
WC 02 **00**  
WC 03 **04**

# Interpreting the Raw Data Stream:

Once you decide an event is valid, you can record the time difference between the signals of the first two panels. This will be the “decay length”.

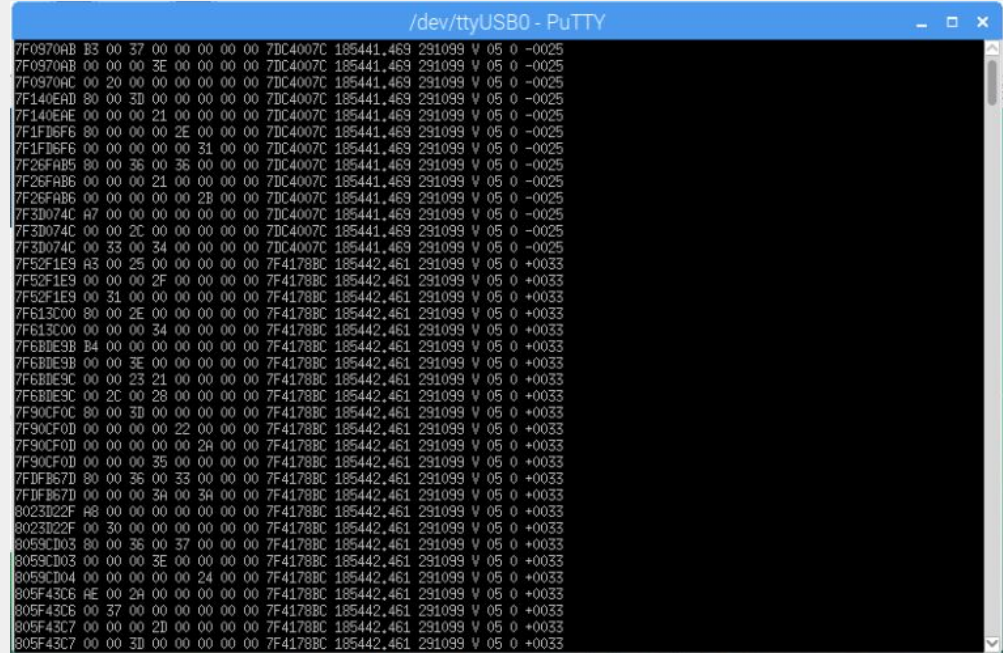

By doing this for several events, you can plot the frequency of events vs the decay length, which will show the number of decays that occur in each time “bin”.

For example, if 20 events had a decay length of 3  $\mu\text{s}$ , you would plot (3, 20).

# Interpreting the Raw Data Stream:

By plotting several data points (usually from 24+ hour runs), you can fit the equation for exponential decay.

$$N(t) = N_0 e^{-\frac{t}{\tau}}$$

```

# Interpreting the Raw Data Stream:

The cosmic ray e-lab allows you to upload the raw data, and “perform a lifetime analysis”, where you can choose parameters and automatically plot and fit the decays.

You can also get the frequency of counts for each time bin if you want to further analyze the data...

# Graphing and fitting the decay:

$$N(t) = N_0 e^{-\frac{t}{\tau}}$$

Manipulating the eq. to reveal a linear relationship:

$$N(t) = N_0 e^{-\frac{t}{\tau}}$$

$$\frac{N(t)}{N_0} = e^{-\frac{t}{\tau}}$$

$$\ln\left(\frac{N(t)}{N_0}\right) = -\frac{t}{\tau}$$

$$\ln(N(t)) - \ln(N_0) = -\frac{t}{\tau}$$

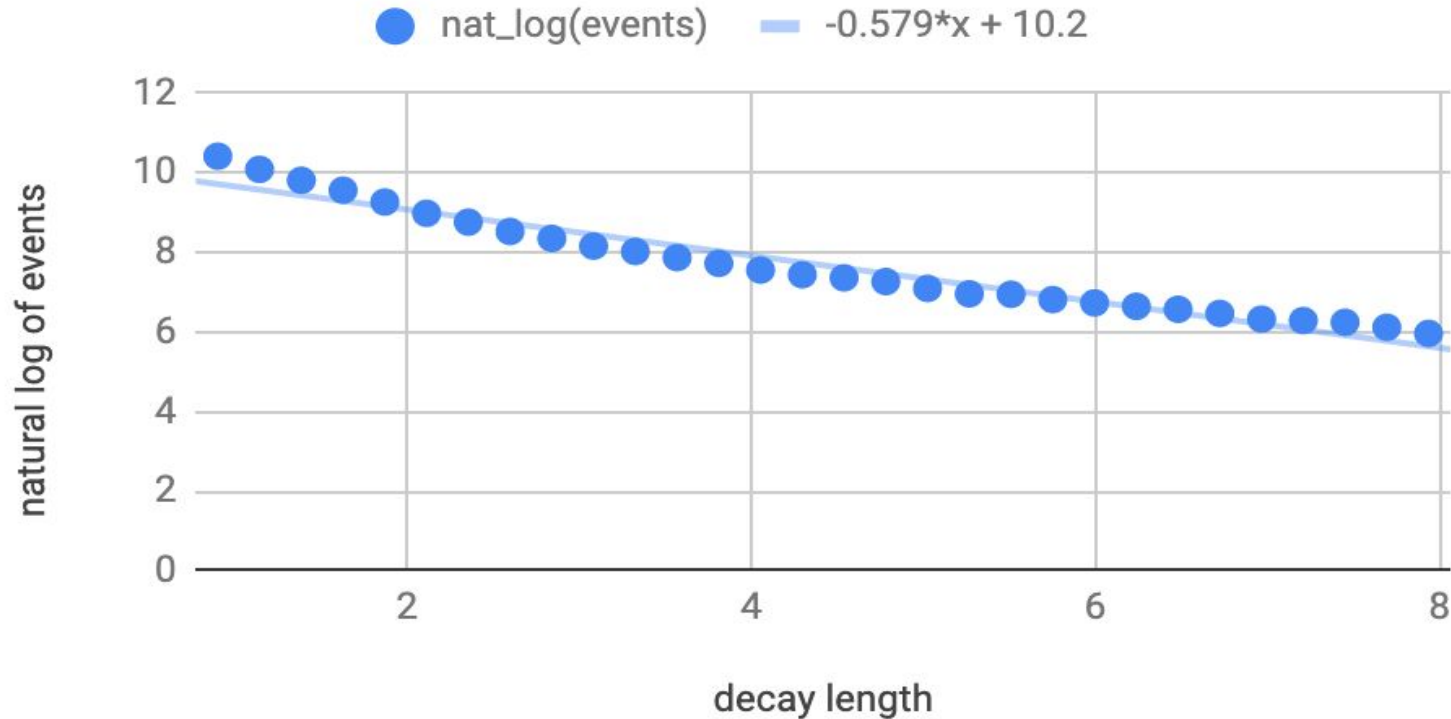

$$\ln(N(t)) = -\frac{t}{\tau} + \ln(N_0)$$

( X-coord, Y-Coord )

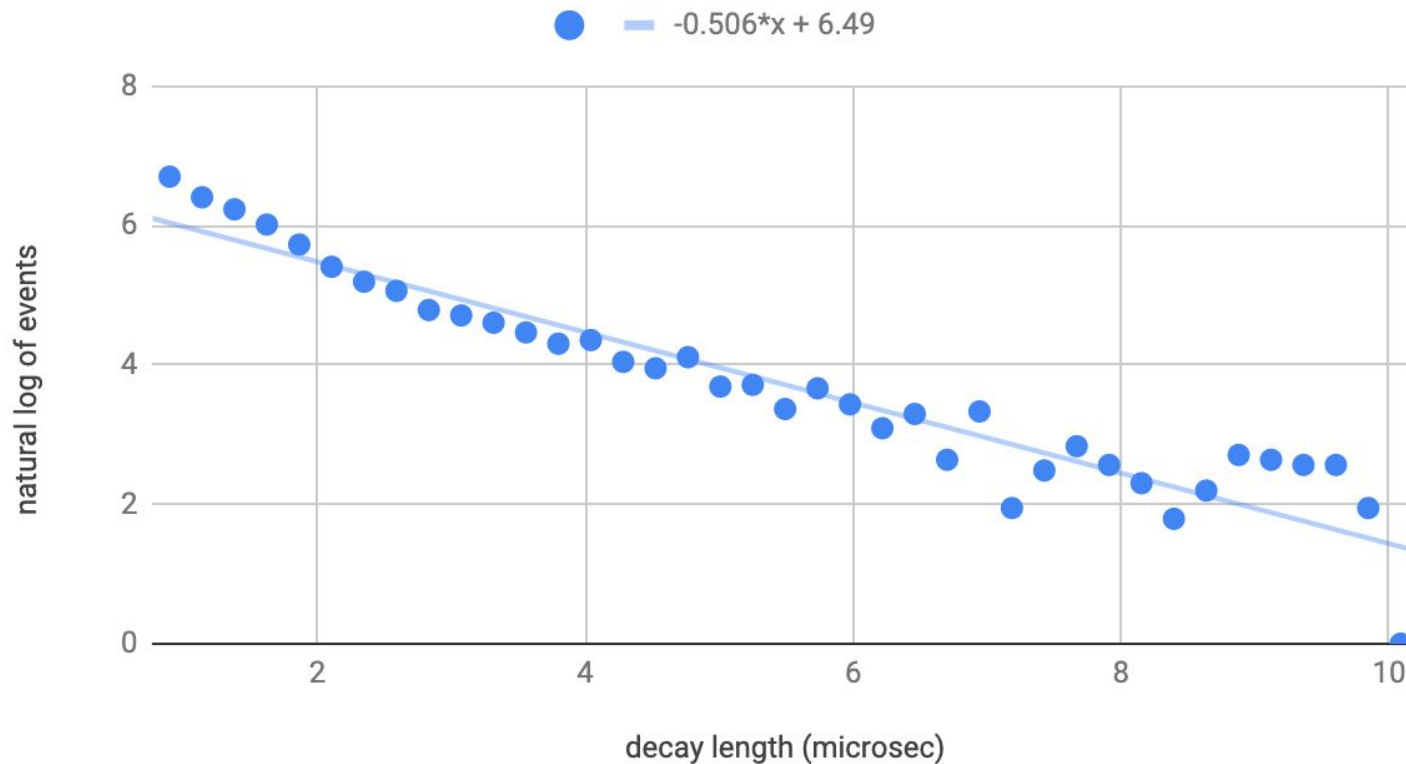

( X-Coord, ln(Y-Coord) )

# natural log of events vs decay length

Measured Mean Lifetime: 1.727  $\mu$ s

## Run with panels separated by 15 cm

Measured Lifetime: 1.976  $\mu$ s

# Connecting our Detector to the Raspberry Pi

The same cables used for a PC will work with a Raspberry! So all you really need is a monitor and a mouse (and an SD card if the board doesn't come with one) to get things set up.

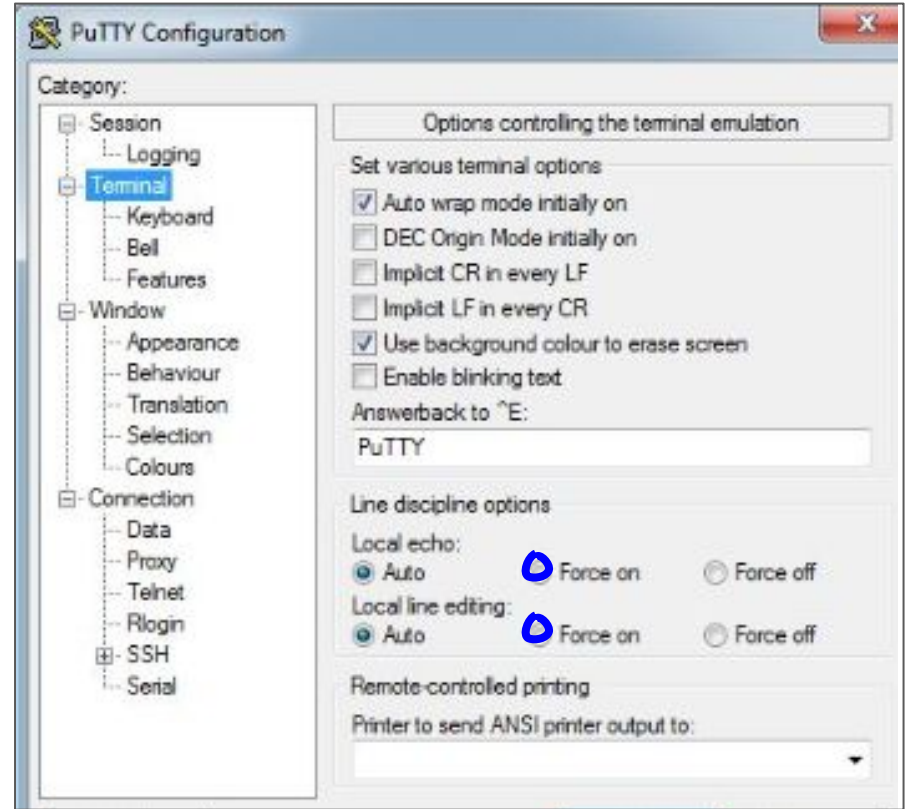

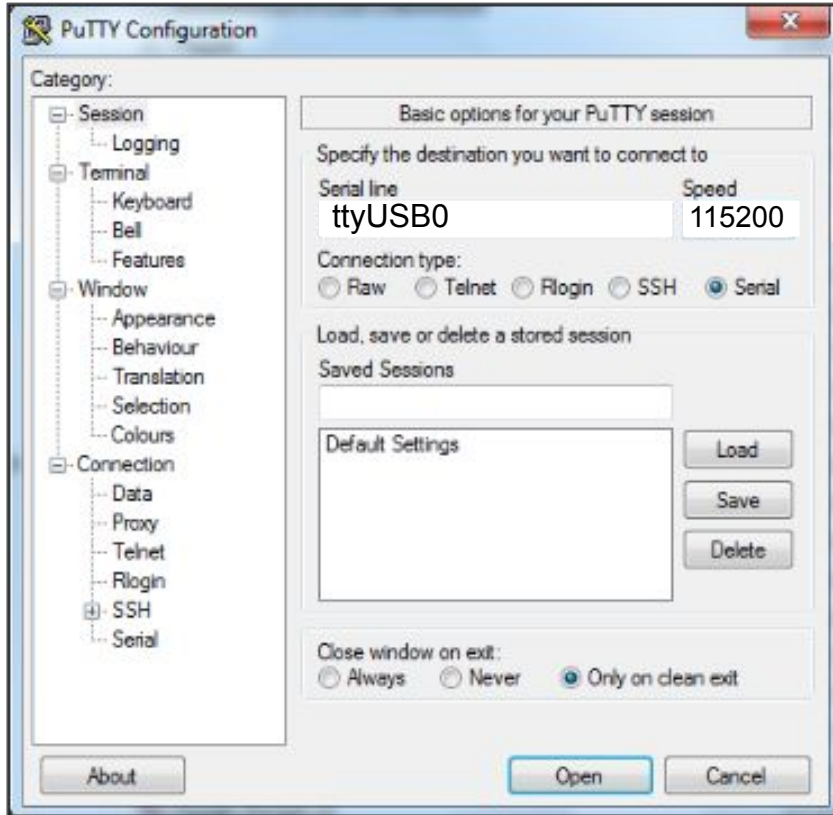

# PuTTY

PuTTY is a free serial terminal emulator that works on the Raspberry Pi (and windows).

Once you install it from the web, you can easily launch it by typing “putty” into the terminal.

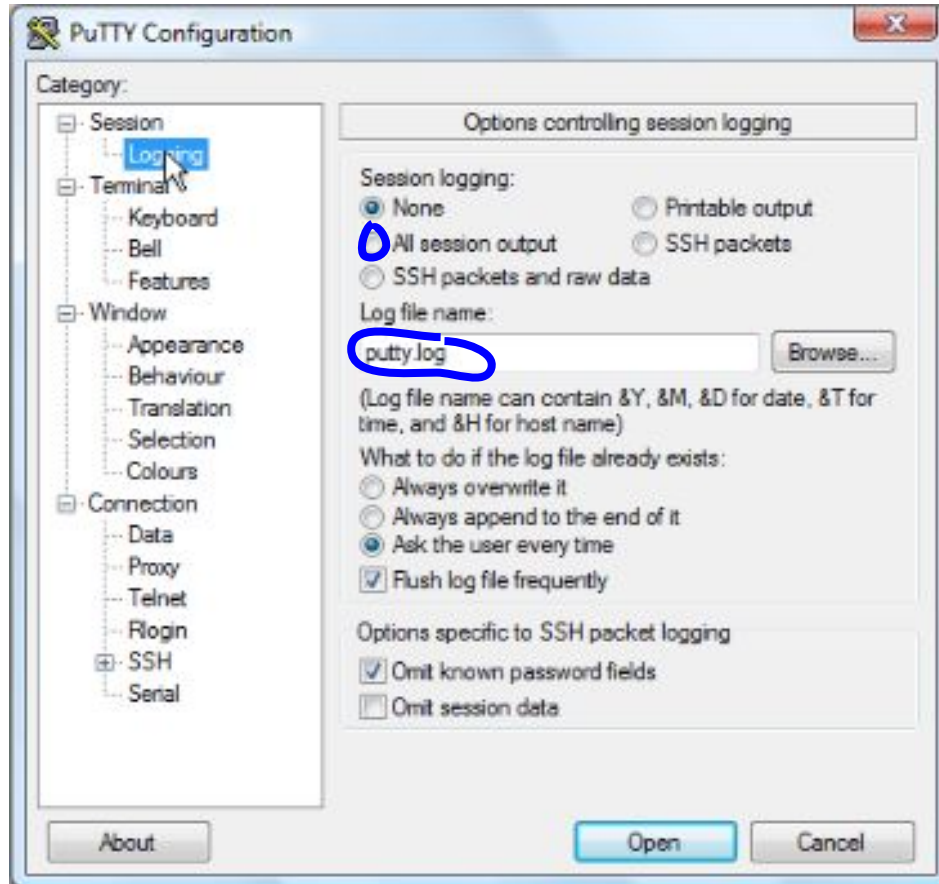

You can easily change the parameters to connect to a serial monitor, and be able to communicate with the DAQ...

# Configuring putty to read out the DAQ...

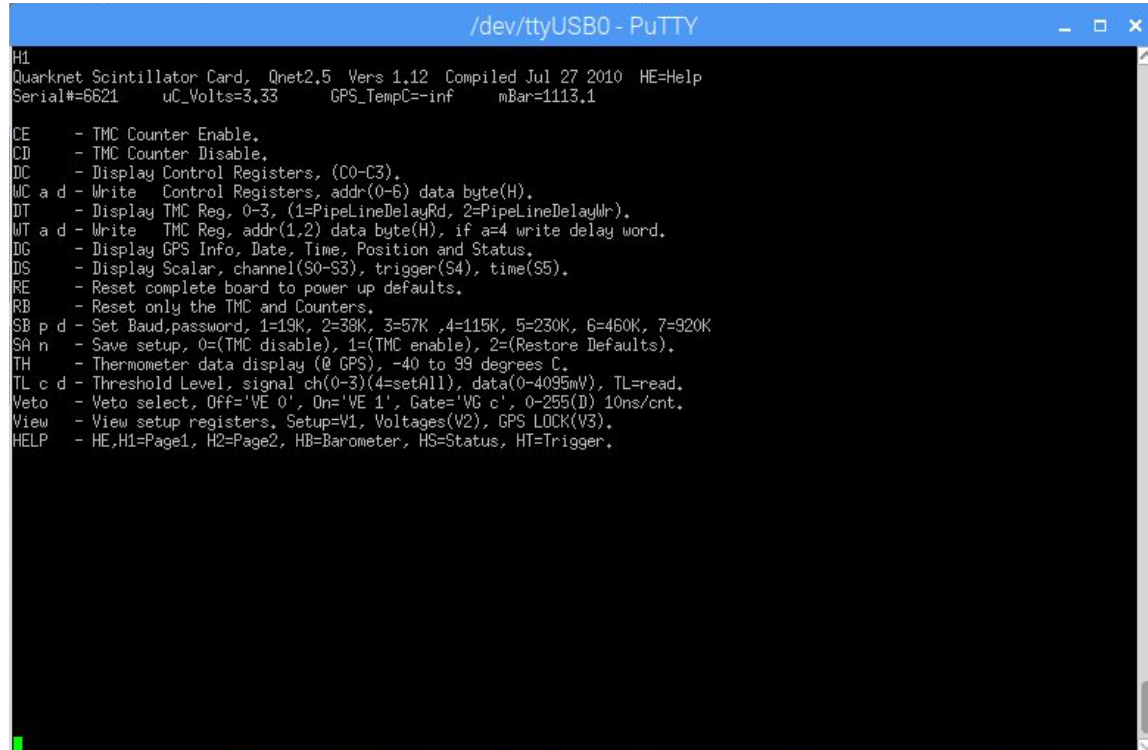

\*These are screenshots of putty from Windows, but it looks the same on a Pi.

# Configuring putty to read out the DAQ...

# And now it works just like a PC!

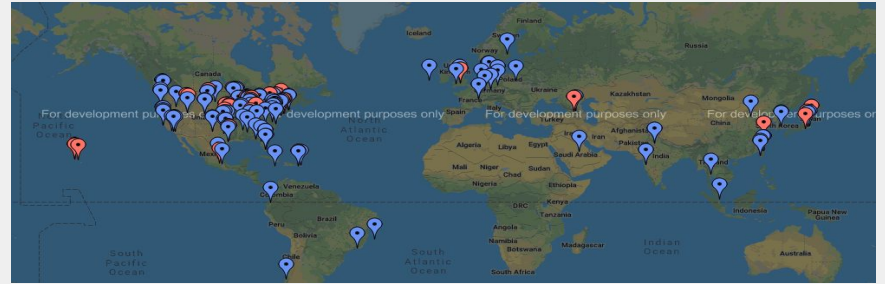

```
/dev/ttyUSB0 - PuTTY
H1
Quarknet Scintillator Card, Qnet2,5 Vers 1.12 Compiled Jul 27 2010 HE=Help
Serial#=6621    uC_Volts=3.33    GPS_TempC=-inf    mBar=1113.1

CE    - TMC Counter Enable.
CD    - TMC Counter Disable.
DC    - Display Control Registers, (C0-C3).
WC a d - Write Control Registers, addr(0-6) data byte(H).
DT    - Display TMC Reg, 0-3, (1=PipeLineDelayRd, 2=PipeLineDelayWr).
WT a d - Write TMC Reg, addr(1,2) data byte(H), if a=4 write delay word.
DG    - Display GPS Info, Date, Time, Position and Status.
DS    - Display Scalar, channel(S0-S3), trigger(S4), time(S5).
RE    - Reset complete board to power up defaults.
RB    - Reset only the TMC and Counters.
SB p d - Set Baud,password, 1=19K, 2=38K, 3=57K ,4=115K, 5=230K, 6=460K, 7=920K
SA n   - Save setup, 0=(TMC disable), 1=(TMC enable), 2=(Restore Defaults).
TH    - Thermometer data display (0 GPS), -40 to 99 degrees C.
TL c d - Threshold Level, signal ch(0-3)(4=setAll), data(0-4095mV), TL=read.
Veto  - Veto select, Off='VE 0', On='VE 1', Gate='VG c', 0-255(D) 10ns/cnt.
View  - View setup registers, Setup=V1, Voltages(V2), GPS LOCK(V3).
HELP  - HE,H1=Page1, H2=Page2, HB=Barometer, HS=Status, HT=Trigger.
```

# Cosmic Ray e-Lab

To make visualizing and interpreting the data much more easy, the Cosmic Ray e-Lab is a free online analysis tool where you can upload the raw data and graph plots showing muon flux, shower studies, and lifetime measurements. The best part of all is that you can see and analyze data of muon detectors from all over the world!

# Conclusion & Related Research

Raspberry pi for large scale events cosmic showers... and to continuously track muon flux compared to air pressure, weather, and other conditions affecting muon tracks.

# Thank you!
